

What is claimed is:

1. A stick type cosmetic material feeding container in which a front cylinder and a base cylinder are coaxially connected in such a manner that the front cylinder and the base cylinder can freely make relative rotations, and a core chuck member retaining a stick type cosmetic material by means of a stick type cosmetic material retaining section is arranged in the front cylinder and which has a feeding mechanism for causing the core chuck member to make a feeding stroke in an axial direction due to the relative rotations of the front cylinder and the base cylinder, wherein a spiral groove is formed on an inner circumferential surface of the base cylinder, and the core chuck member comprising:

a shaft extending from the stick type cosmetic material retaining section;

a cylindrical body which is installed at an edge of the shaft, comes into contact with a part of the front cylinder and a part of the base cylinder at an advance limit and a retreat limit of a feeding stroke of the core chuck member, respectively, and defines the advance limit and the retreat limit, respectively;

an engagement projection which is installed at an outer circumference of the cylindrical body and elastically and spirally engaged with the spiral groove; and

a shock absorbing section which is formed at the cylindrical body and absorbs a shock in an axial direction,
and wherein when the engagement projection goes over the spiral

groove and makes a clutch rotation due to a further rotary load on the core chuck member at least at the retreat limit of the core chuck member, the shock absorbing section absorbs a shock in an axial direction to the core chuck member which has arisen resulting from the clutch rotation.

2. A stick type cosmetic material feeding container according to claim 1, wherein the spiral groove to be formed at an inner circumference of the base cylinder is formed as a roulette-shaped spiral, an outside diameter of the cylindrical body is slightly smaller than an inside diameter of the roulette-shaped spiral in the base cylinder, and the engagement projection is spirally engaged with a root of the roulette-shaped spiral.

3. A stick type cosmetic material feeding container according to claim 2, wherein the engagement projection to be installed at an outer circumference of the cylindrical body is installed on a fraction provided between a pair of parallel slits which are inclined in the same direction as that of a slope of the roulette-shaped spiral of the base cylinder.

4. A stick type cosmetic material feeding container according to claim 2, wherein the engagement projection to be installed at an outer circumference of the cylindrical body is installed on a fraction provided among a plurality of slits which extend in an axial direction at an edge of the cylindrical body.

5. A stick type cosmetic material feeding container according to claim 1, wherein the shock absorbing section to be installed at the cylindrical body is constituted as a hooked slit formed at the cylindrical body.

6. A stick type cosmetic material feeding container according to claim 1, wherein the shock absorbing section to be installed at the cylindrical body is constituted as a spiral slit formed at the cylindrical body.

7. A stick type cosmetic material feeding container according to claim 1, wherein a plurality of slide grooves extending in an axial direction are provided at the front cylinder, a plurality of claws for retaining the stick type cosmetic material are arranged as the stick type cosmetic material retaining section at a front end of the core chuck member, and the claws are located at the plurality of slide grooves in the front cylinder and guide the core chuck member so that the core chuck member can move only in an axial direction along an inner circumference of the front cylinder.
